## 1 Hash functions and multiplanes

In this lab, we are going to practice the most important concepts related to the hash functions explained in the videos. You will be using these in this week's assignment.

A key point for the lookup using hash functions is the calculation of the hash key or bucket id that we assign for a given entry. In this notebook, we will cover:

- Basic hash tables
- Multiplanes
- Random planes

#### 1.1 Basic Hash tables

Hash tables are data structures that allow indexing data to make lookup tasks more efficient. In this part, you will see the implementation of the simplest hash function.

In the next cell, we will define a straightforward hash function for integer numbers. The function will receive a list of integer numbers and the desired amount of buckets. The function will produce a hash table stored as a dictionary, where keys contain the hash keys, and the values will provide the hashed elements of the input list.

The hash function is just the remainder of the integer division between each element and the desired number of buckets.

```
[2]: def basic_hash_table(value_l, n_buckets):

def hash_function(value, n_buckets):
    return int(value) % n_buckets

hash_table = {i:[] for i in range(n_buckets)} # Initialize all the buckets⊔
    →in the hash table as empty lists
```

```
for value in value_1:
    hash_value = hash_function(value,n_buckets) # Get the hash key for the_

sqiven value
    hash_table[hash_value].append(value) # Add the element to the_

scorresponding bucket

return hash_table
```

Now let's see the hash table function in action. The pretty print function (pprint()) will produce a visually appealing output.

In this case, the bucket key must be the rightmost digit of each number.

#### 1.2 Planes

Multiplanes hash functions are other types of hash functions. Multiplanes hash functions are based on the idea of numbering every single region that is formed by the intersection of n planes. In the following code, we show the most basic forms of the multiplanes principle. First, with a single plane:

```
[4]: P = np.array([[1, 1]]) # Define a single plane.
fig, ax1 = plt.subplots(figsize=(8, 8)) # Create a plot

plot_vectors([P], axes=[2, 2], ax=ax1) # Plot the plane P as a vector

# Plot random points.
for i in range(0, 10):
    v1 = np.array(np.random.uniform(-2, 2, 2)) # Get a pair of random_u

numbers between -2 and 2

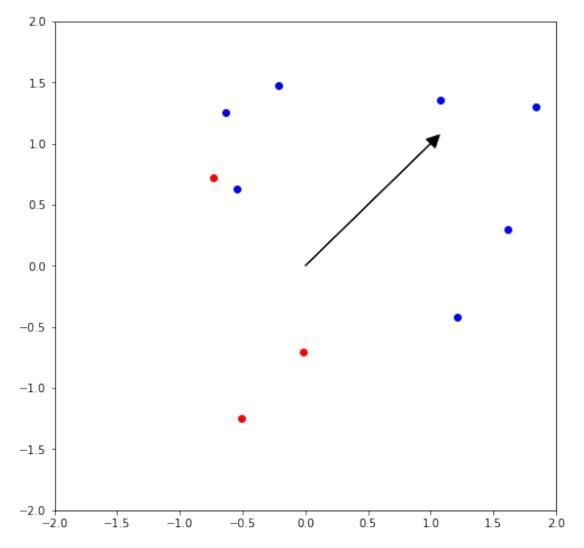

side_of_plane = np.sign(np.dot(P, v1.T))
```

```
# Color the points depending on the sign of the result of np.dot(P,□
→point.T)

if side_of_plane == 1:
        ax1.plot([v1[0]], [v1[1]], 'bo') # Plot blue points

else:
        ax1.plot([v1[0]], [v1[1]], 'ro') # Plot red points

plt.show()
```

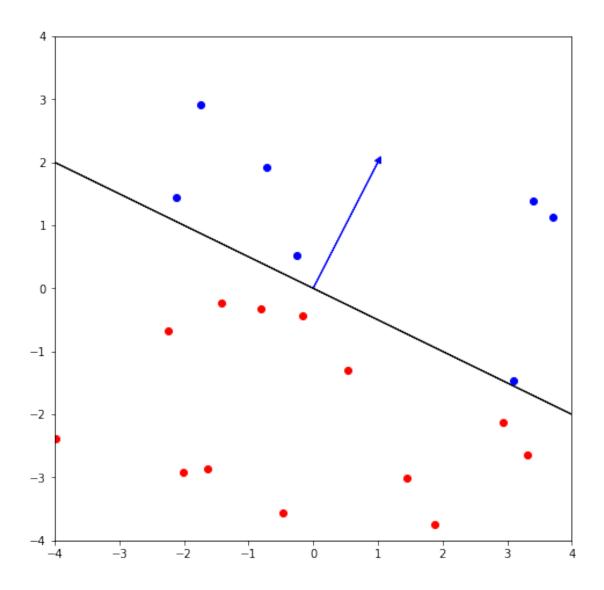

The first thing to note is that the vector that defines the plane does not mark the boundary between the two sides of the plane. It marks the direction in which you find the 'positive' side of the plane. Not intuitive at all!

If we want to plot the separation plane, we need to plot a line that is perpendicular to our vector P. We can get such a line using a  $90^{\circ}$  rotation matrix.

Feel free to change the direction of the plane P.

```
[5]: P = np.array([[1, 2]]) # Define a single plane. You may change the direction
     # Get a new plane perpendicular to P. We use a rotation matrix
     PT = np.dot([[0, 1], [-1, 0]], P.T).T
     fig, ax1 = plt.subplots(figsize=(8, 8)) # Create a plot with custom size
     plot_vectors([P], colors=['b'], axes=[2, 2], ax=ax1) # Plot the plane P as a_
      \rightarrowvector
     # Plot the plane P as a 2 vectors.
     # We scale by 2 just to get the arrows outside the current box
     plot_vectors([PT * 4, PT * -4], colors=['k', 'k'], axes=[4, 4], ax=ax1)
     # Plot 20 random points.
     for i in range(0, 20):
             v1 = np.array(np.random.uniform(-4, 4, 2)) # Get a pair of random_
      \rightarrownumbers between -4 and 4
             side_of_plane = np.sign(np.dot(P, v1.T)) # Get the sign of the dot_
      \rightarrowproduct with P
             # Color the points depending on the sign of the result of np.dot(P, \square
      \rightarrow point.T)
             if side of plane == 1:
                  ax1.plot([v1[0]], [v1[1]], 'bo') # Plot a blue point
             else:
                  ax1.plot([v1[0]], [v1[1]], 'ro') # Plot a red point
     plt.show()
```

Now, let us see what is inside the code that color the points.

```
[6]: P = np.array([[1, 1]])  # Single plane
v1 = np.array([[1, 2]])  # Sample point 1
v2 = np.array([[-1, 1]])  # Sample point 2
v3 = np.array([[-2, -1]])  # Sample point 3
```

```
[7]: np.dot(P, v1.T)
```

[7]: array([[3]])

```
[32]: np.dot(P, v2.T)
```

[32]: array([[0]])

```
[33]: np.dot(P, v3.T)
[33]: array([[-3]])
     The function below checks in which side of the plane P is located the vector v
[34]: def side_of_plane(P, v):
          dotproduct = np.dot(P, v.T) # Get the dot product P * v'
          sign_of_dot_product = np.sign(dotproduct) # The sign of the elements of the_
       \rightarrow dotproduct matrix
          sign_of_dot_product_scalar = sign_of_dot_product.item() # The value of the_u
       \hookrightarrow first item
          return sign_of_dot_product_scalar
[35]: side_of_plane(P, v1) # In which side is [1, 2]
[35]: 1
[36]: side_of_plane(P, v2) # In which side is [-1, 1]
[36]: 0
[37]: side_of_plane(P, v3) # In which side is [-2, -1]
[37]: -1
```

### 1.3 Hash Function with multiple planes

In the following section, we are going to define a hash function with a list of three custom planes in 2D.

```
[38]: P1 = np.array([[1, 1]])  # First plane 2D
P2 = np.array([[-1, 1]])  # Second plane 2D
P3 = np.array([[-1, -1]])  # Third plane 2D
P_1 = [P1, P2, P3]  # List of arrays. It is the multi plane

# Vector to search
v = np.array([[2, 2]])
```

The next function creates a hash value based on a set of planes. The output value is a combination of the side of the plane where the vector is localized with respect to the collection of planes.

We can think of this list of planes as a set of basic hash functions, each of which can produce only 1 or 0 as output.

```
[39]: def hash_multi_plane(P_1, v):
    hash_value = 0
```

```
for i, P in enumerate(P_1):
    sign = side_of_plane(P,v)
    hash_i = 1 if sign >=0 else 0
    hash_value += 2**i * hash_i
return hash_value
```

```
[40]: hash_multi_plane(P_1, v) # Find the number of the plane that containes this →value
```

[40]: 3

#### 1.4 Random Planes

[[ 1.76405235 0.40015721]

In the cell below, we create a set of three random planes

The next function is similar to the side\_of\_plane() function, but it evaluates more than a plane each time. The result is an array with the side of the plane of v, for the set of planes P

```
[43]: # Side of the plane function. The result is a matrix

def side_of_plane_matrix(P, v):
    dotproduct = np.dot(P, v.T)
    sign_of_dot_product = np.sign(dotproduct) # Get a boolean value telling if
    → the value in the cell is positive or negative
    return sign_of_dot_product
```

Get the side of the plane of the vector [2, 2] for the set of random planes.

```
[44]: array([[1.], [1.],
```

[1.]])

Now, let us use the former function to define our multiplane hash function

```
[45]: def hash_multi_plane_matrix(P, v, num_planes):
    sides_matrix = side_of_plane_matrix(P, v) # Get the side of planes for P
→ and v
    hash_value = 0
    for i in range(num_planes):
        sign = sides_matrix[i].item() # Get the value inside the matrix cell
        hash_i = 1 if sign >=0 else 0
        hash_value += 2**i * hash_i # sum 2^i * hash_i

return hash_value
```

Print the bucket hash for the vector v = [2, 2].

```
[46]: hash_multi_plane_matrix(random_planes_matrix, v, num_planes)
```

[46]: 7

**Note** This showed you how to make one set of random planes. You will make multiple sets of random planes in order to make the approximate nearest neighbors more accurate.

#### 1.5 Document vectors

Before we finish this lab, remember that you can represent a document as a vector by adding up the word vectors for the words inside the document. In this example, our embedding contains only three words, each represented by a 3D array.

[1 0 3]

Congratulations! You've now completed this lab on hash functions and multiplanes!
